
SESSION 4 – API Testing (Basic Intro) + Database SQL Testing

1. Use the online API testing tool ReqRes (<https://reqres.in/>) to make a GET request to `/api/users/2` and note down the response status code and the returned user's first name.

ANS:

- Executed a GET request on the endpoint `/api/users/2` using ReqRes.
- The API returned a successful response with status code 200 OK.
- User information was received in JSON format.
- The first name returned in the response was Janet.

2. Send a POST request using ReqRes to `/api/users` with JSON data `{"name": "Virat", "job": "Cricketer"}` and write down the response code and the id value returned in the response.

ANS:

- Sent a POST request to `/api/users` with the following JSON payload:

```
{  
  "name": "Virat",  
  "job": "Cricketer"  
}
```

- The API responded with status code 201 Created.
- A new user record was created successfully.
- The response contained a generated ID and creation timestamp.

3. Given the following JSON response from an API: {"id": 101, "name": "Pizza Hut", "location": "Ahmedabad"}, write the SQL INSERT statement to add this restaurant to a table named restaurants with columns id, name, and location.

ANS:

```
INSERT INTO restaurants (id, name, location)
VALUES (101, 'Pizza Hut', 'Ahmedabad');
```

- This query adds a new record into the restaurants table.
- The values are inserted into the id, name, and location columns.
- The restaurant information is stored successfully in the database.

4. Suppose you have a users table in your database and the UI shows a new user 'Riya' was registered. Write an SQL SELECT query to confirm if 'Riya' exists in the users table, and explain what result you would expect if the UI and DB are in sync.

ANS:

```
SELECT * FROM users
WHERE name = 'Riya';
```

- This query is used to verify whether the user "Riya" exists in the users table.
- If the registration process is successful, the query should return Riya's record.
- If no data is returned, it may indicate that the user was not added to the database.

5. After deleting a product from your shopping cart in the Flipkart UI, write an SQL query to verify that the product is no longer present in the `cart_items` table for your user.

Hint: Use `SELECT` to check for the `product_id` and your `user_id` in `cart_items`.

ANS:

```
SELECT * FROM cart_items  
WHERE product_id = 101  
AND user_id = 1001;
```

- This query checks whether the deleted product still exists in the user's cart.
- If the product removal was successful, the query should return zero records.
- If a record is returned, it means the product is still present in the database.
